

# Applying template synthesis to the radio emission from air showers with different geometries

Mitja Desmet, Stijn Buitink, Tim Huege  
ARENA conference (11–14 Jun 2024)

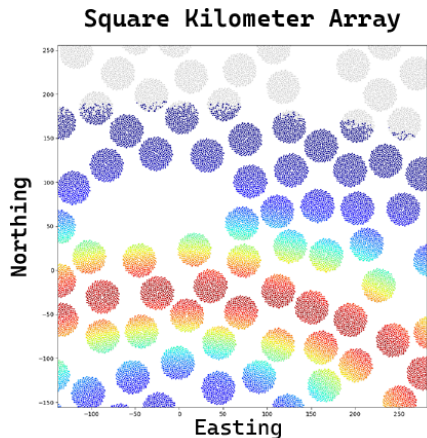

# MICROSCOPIC SIMULATIONS ARE ACCURATE, BUT COMPUTATIONALLY INEFFICIENT

Traditionally we use Monte-Carlo based simulations in order to interpret our data.

- ▶ This becomes intractable for the next generation of cosmic ray experiments such as SKA.

To tackle this, we developed a hybrid approach: **template synthesis**

## ATMOSPHERIC SLICES IN TEMPLATE SYNTHESIS ARE POINT SOURCES OF RADIO EMISSION

In the template synthesis approach, we divide the atmosphere into **slices** of constant atmospheric depth.

- ▶ Each slice is labelled by the atmospheric depth at the bottom of the slice.

The emission coming from each slice is **treated separately**.

- ▶ The amplitude is rescaled with the number of (emitting) particles in the slice.

# TEMPLATE SYNTHESIS PARAMETRISES THE EMISSION TO REDUCE COMPUTATION TIME

## Geomagnetic component

## Charge-excess/Askaryan component

# WE HAVE SHOWN THIS WORKS FOR A FIXED ZENITH ANGLE

Generalising template synthesis of EAS radio emission  
to other geometries

---

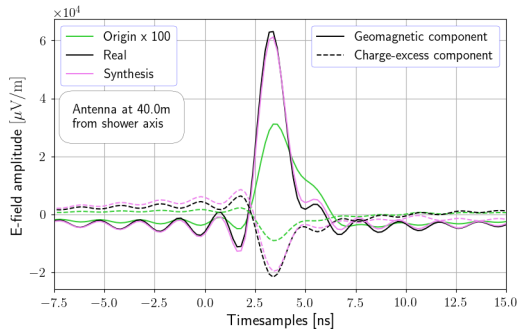

Mitja Desmet,<sup>a,\*</sup> Stijn Buitink<sup>a</sup> and Tim Huege<sup>a,b</sup>

## WE HAVE SHOWN THIS WORKS FOR A FIXED ZENITH ANGLE

We input an **origin** shower and use the parametrisations to synthesise a **target** longitudinal profile.

The **synthesised** pulse matches the one from **CoREAS** within 6% in amplitude.

## IN ORDER TO MAKE TEMPLATE SYNTHESIS VIABLE, WE NEED TO GENERALISE IT ACROSS GEOMETRIES

The current formulation of **template synthesis** does not allow for translating across air shower geometries (i.e. zenith and azimuth angle).

## IN ORDER TO MAKE TEMPLATE SYNTHESIS VIABLE, WE NEED TO GENERALISE IT ACROSS GEOMETRIES

The current formulation of **template synthesis** does not allow for translating across air shower geometries (i.e. zenith and azimuth angle).

Combining slice and antenna in one quantity

**Viewing angle**

# THE VIEWING ANGLE AS FRACTION OF CHERENKOV ANGLE IS A COMPARABLE QUANTITY

- ▶ Shower axis
- ▶  $N(X)$  : longitudinal profile
- ▶  $\Delta X_{max}$  : distance from  $X_{max}$  to slice, in  $\text{g}/\text{cm}^2$
- ▶  $\theta_V$  : viewing angle, as a fraction of  $\theta_C$
- ▶ Shower plane
- ▶ Antenna projection

# THE $\Delta X_{\text{MAX}}$ DETERMINES THE EQUIVALENT SLICE IN A DIFFERENT GEOMETRY

$$\Delta X_{\text{max}} = 200 \text{ g/cm}^2, \theta_V = 0.8 \theta_C$$

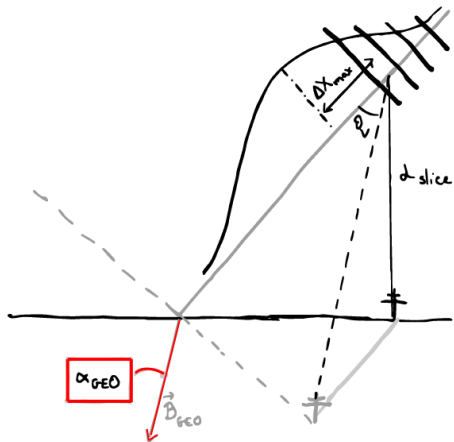

# THE EQUIVALENT SLICE STILL HAS DIFFERENT PROPERTIES THAT AFFECT THE AMPLITUDE

►  $d_{\text{slice}}$  : distance slice - antenna

# THE EQUIVALENT SLICE STILL HAS DIFFERENT PROPERTIES THAT AFFECT THE AMPLITUDE

- ▶  $d_{slice}$  : distance slice - antenna
- ▶  $\alpha_{GEO}$  : geomagnetic angle

# THE EQUIVALENT SLICE STILL HAS DIFFERENT PROPERTIES THAT AFFECT THE AMPLITUDE

- ▶  $d_{slice}$  : distance slice - antenna
- ▶  $\alpha_{GEO}$  : geomagnetic angle
- ▶  $N_{slice}$  : # of emitters in slice
- ▶  $\rho_{slice}$  : density in slice
- ▶  $\theta_{slice}^C$  : Cherenkov angle at slice

# THE EQUIVALENT SLICE STILL HAS DIFFERENT PROPERTIES THAT AFFECT THE AMPLITUDE

- ▶  $d_{\text{slice}}$  : distance slice - antenna
- ▶  $\alpha_{\text{GEO}}$  : geomagnetic angle
- ▶  $N_{\text{slice}}$  : # of emitters in slice
- ▶  $\rho_{\text{slice}}$  : density in slice
- ▶  $\theta_{\text{slice}}^{\text{C}}$  : Cherenkov angle at slice
- ▶  $\theta, \phi$  : zenith/azimuth of shower

## WE RELATE THE SPECTRUM TO THE PROPERTIES OF THE SLICE

The **geomagnetic** amplitude frequency spectrum an antenna observes coming from a given atmospheric slice, scales with

- ▶ the **geomagnetic angle** (for the geomagnetic component),  $\propto \sin(\alpha_{\text{GEO}})$
- ▶ the **air density**<sup>1</sup>,  $\propto 1/\rho_{\text{slice}}$

For the **charge-excess** emission we have a scaling with

- ▶ The **Cherenkov angle**<sup>1</sup> (related to the refractive index),  $\propto \sin(\theta_{\text{slice}}^{\text{C}})$

**Both** components also scale with

- ▶ the **distance** to the slice,  $\propto 1/d_{\text{slice}}$
- ▶ the number of **particles** in the slice, as  $\propto N_{\text{slice}}$

---

# APPLYING THESE SCALING RELATIONS, ALIGNS THE SPECTRA FROM THE EQUIVALENT SLICES

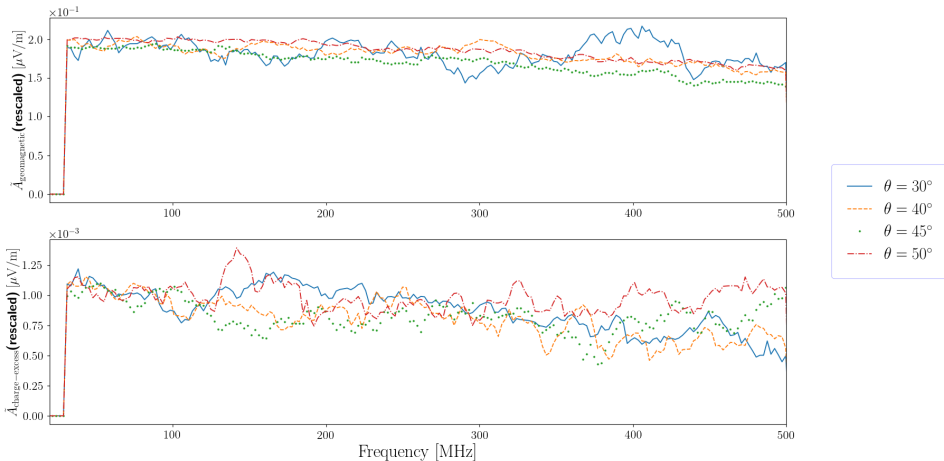

**Before:**

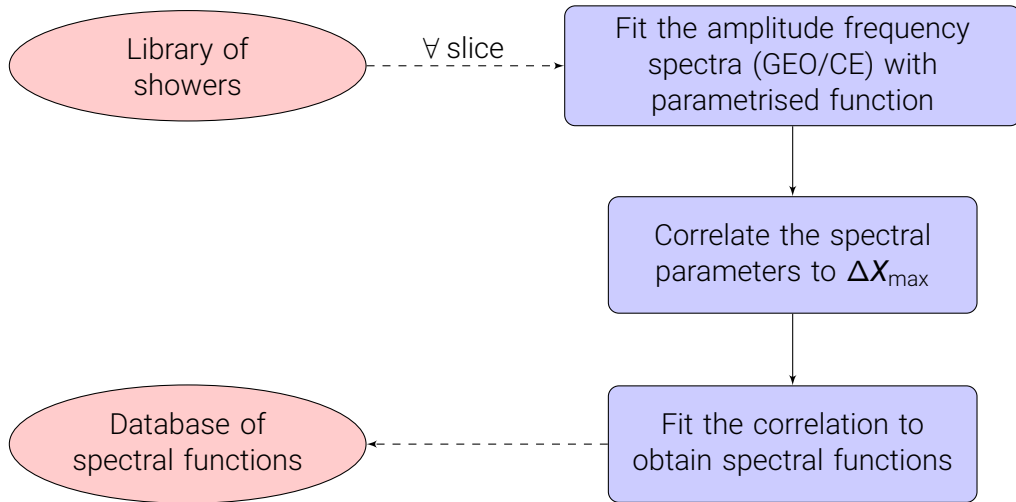

# APPLYING THESE SCALING RELATIONS, ALIGNS THE SPECTRA FROM THE EQUIVALENT SLICES

After:

$$\Delta X_{\max} = 200 \text{ g/cm}^2, \theta_V = 0.8 \theta_C$$

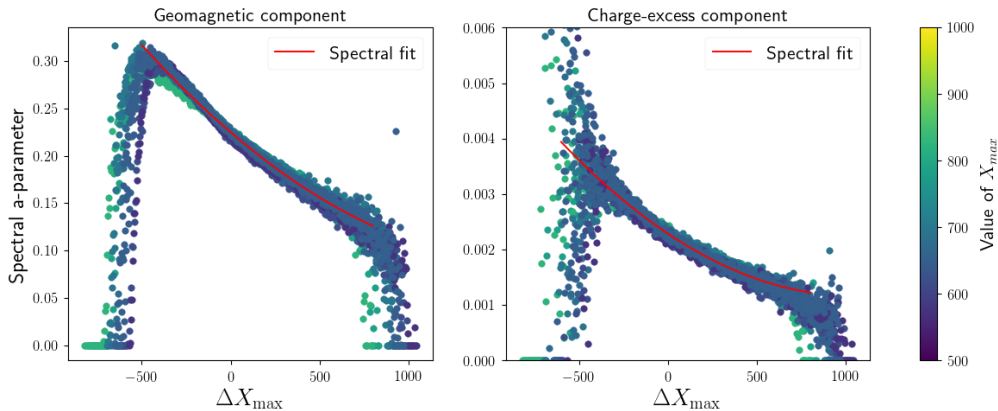

## NOW WE CAN APPLY THE STANDARD TEMPLATE SYNTHESIS MACHINERY

## WE FIND SPECTRAL FUNCTIONS PER VIEWING ANGLE

If we correlate the values of the parameters from the parametrised function to the  $\Delta X_{\max}$  of the slice they were extracted from, they all fall onto a parabola.

## TO SYNTHESISE THE EMISSION IN AN ANTENNA, WE USE INTERPOLATION IN EVERY SLICE

We can now **synthesise** the emission **per slice** for the viewing angles we have the spectral functions for.

For every slice, a viewing angle will result in a different distance in the shower plane.

- ▶ Viewing angles are function of Cherenkov angle, which varies per slice.
- ▶ Distance to the showerplane also changes.

**Solution:** interpolate<sup>a</sup> to the required viewing angle per slice

# GEOMAGNETIC SIGNAL SYNTHESIS WELL, CHARGE-EXCESS COMPONENT NEEDS ADJUSTMENTS

Signals for an antenna at 240.0m from the shower axis

$$X_{\max}^{\text{origin}} = 667.0 \text{ g/cm}^2 - X_{\max}^{\text{target}} = 611.8 \text{ g/cm}^2$$

Geomagnetic component

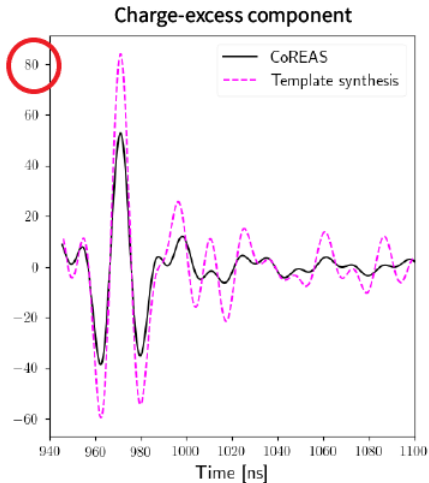

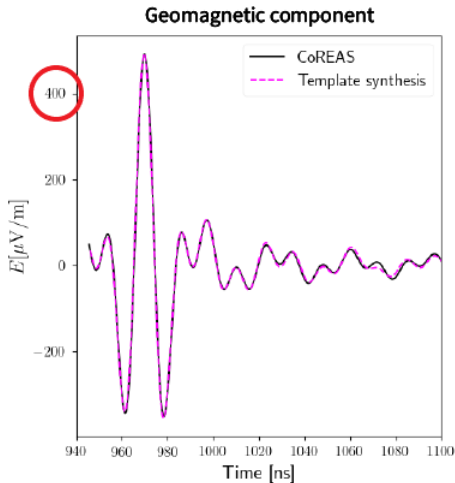

Charge-excess component

# GEOMAGNETIC SIGNAL SYNTHESIS WELL, CHARGE-EXCESS COMPONENT NEEDS ADJUSTMENTS

Signals for an antenna at 240.0m from the shower axis

$$X_{\max}^{\text{origin}} = 667.0 \text{ g/cm}^2 - X_{\max}^{\text{target}} = 611.8 \text{ g/cm}^2$$

## OPEN QUESTION: SHOWERPLANE PROJECTION

**How should one project to the showerplane?**

- ▶ Along the **shower axis**?
- ▶ Or rather along **line of sight**?

## TAKE-HOME MESSAGE

We found a set of **scaling relations** which relate the amplitude frequency spectra from slices of showers with a different zenith angle.

- ▶ Key components are the viewing angle,  $\theta_v$ , and the distance of the slice to the shower maximum,  $\Delta X_{\max}$ .

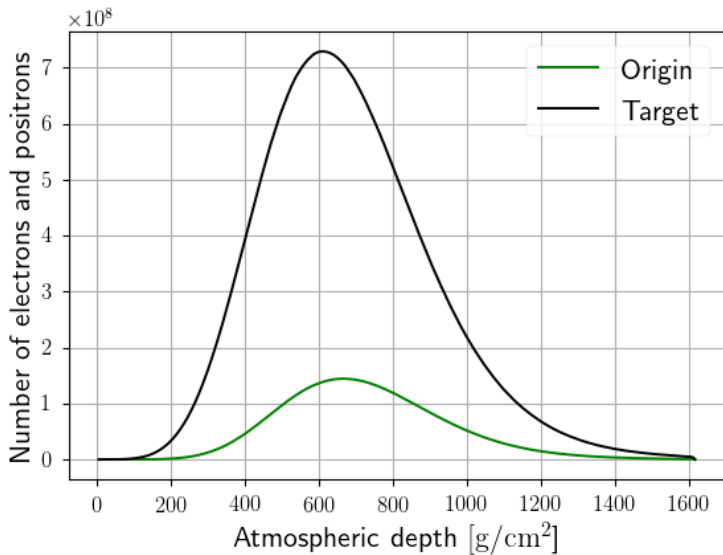

Combining these with a geometry based on viewing angle, we can

- remove the dependency on the slice,
- reduce the number of parameters to store and
- generalise the spectral functions for all geometries.

⇒ **We are ready to apply template synthesis to cosmic ray air showers** from any arrival direction, which will allow us **to simulate the radio emission at macroscopic simulation speeds**, complementary to Radio Morphing.

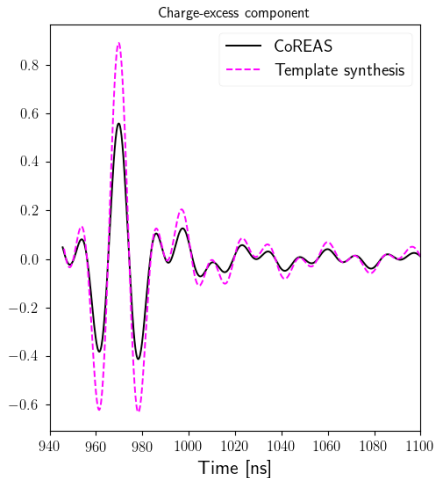

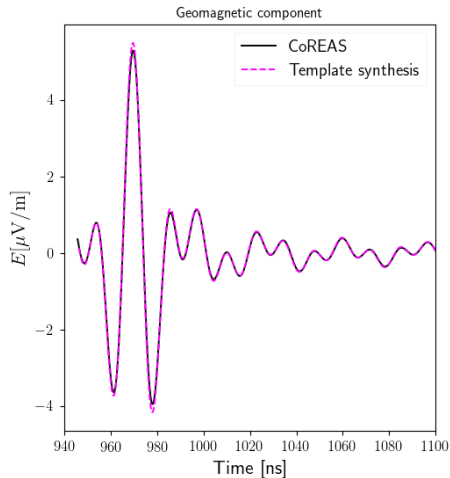

**Thank you!**
